

Effects of being stopped by the police by age 14 on the probability of attending university*

Binomial logistic regression models estimated using maximum likelihood.
Marginal effects at the mean (i.e., in probability scale)
and 95% confidence intervals reported.

* Dependent variable: self-reported likelihood to attend university,
dichotomised on the 75th percentile (likely vs. not likely).

Models include previous educational motivation by age 14.
Models also control for gender, perception of safety, gang membership by age 14,
cannabis use by age 14, drinking by age 14, and victimisation by age 14.

n = 5050
